LDBC Social Network Benchmark (SNB) - v0.1.4 First Public Draft Release v0.1.4

Coordinator: [Arnau Prat (UPC)]

With contributions from: [Peter Boncz (VUA), Josep Lluís Larriba (UPC), Renzo Angles (TALCA), Alex Averbuch (NEO), Orri Erling (OGL), Andrey Gubichev (TUM), Mirko Spasić (OGL)], Minh-Duc Pham (VUA), Norbert Martínez (SPARSITY)

Abstract

LDBC's Social Network Benchmark (LDBC-SNB) is an effort intended to test various functionalities of systems used for graph-like data management. For this, LDBC-SNB uses the recognizable scenario of operating a social network, characterized by its graph-shaped data.

LDBC-SNB consists of three sub-benchmarks, or workloads, that focus on different functionalities. In this document, a preliminary version of the Interactive Workload, which contains lookup queries, is presented. The other workloads, still in development, are the Business Intelligence Workloads (with analytical queries), and the Graph Analytics Workload (with graph algorithms).

This document contains a detailed explanation of the data used in the whole LDBC-SNB benchmark, a detailed description for all the Interactive Workload lookup queries, and instructions on how to generate the data and run the benchmark with the provided software.

Executive Summary

The new data economy era, based on complexly structured, distributed and large datasets, has brought on new demands on data management and analytics. As a consequence, new industry actors have appeared, offering technologies specially build for the management of graph-like data. Also, traditional database technologies, such as relational databases, are being adapted to the new demands to remain competitive.

LDBC's Social Network Benchmark (LDBC-SNB) is an industry and academia initiative, formed by principal actors in the field of graph-like data management. His goal is to define a framework where different graph based technologies can be fairly tested and compared, that can drive the identification of systems' bottlenecks and required functionalities, and can help researchers to open new research lines.

The philosophy around which LDBC-SNB is being designed is to be easy to understand, to be felxible and to be cheap to adopt. For all these reasons, LDBC-SNB will propose different workloads representing all the usage scenarios of graph-like database technologies, hence, targeting systems of different nature and characteristics. In order increase its adoption by industry and reasearch institutions, LDBC-SNB provides all the necessary software, which are designed to be easy to use and deploy at a small cost.

This preliminary version of the LDBC-SNB specification, contains a detailed explanation of the data used in the whole LDBC-SNB benchmark, a detailed description for all the Interactive Workload lookup queries, and instructions on how to generate the data and run the benchmark with the provided software.

Table of Contents

List of Figures

Definitions

DATAGEN: Is the data generator provided by the LDBC-SNB, which is responsible of generating the data needed to run the benchmark.

DBMS: A DataBase Management System.

LDBC-SNB: Linked Data Benchmark Council Social Network Benchmark.

Query Mix: Refers to the ratio between read and update queries of a workload, and the frequency at which they are issued.

SF (Scale Factor): The LDBC-SNB is designed to target systems of different size and scale. The scale factor determines the size of the data used to run the benchmark, in terms of Gigabytes.

SUT: The System Under Test is defined to be the database system where the benchmark is executed.

Test Driver: A program provided by the LDBC-SNB, which is responsible of executing the different workloads and gathering the results.

Test Sponsor: The Test Sponsor is the company officially submitting the Result with the FDR and will be charged the filing fee. Although multiple companies may sponsor a Result together, for the purposes of the LDBC processes the Test Sponsor must be a single company. A Test Sponsor need not be a LDBC member. The Test Sponsor is responsible for maintaining the FDR with any necessary updates or corrections. The Test Sponsor is also the name used to identify the Result.

Workload: A workload refers to a set of queries of a given nature (i.e interactive, analytical, business), how they are issued and at which rate.

1.1 Motivation for the Benchmark

The new era of data economy, based on large, distributed and complexly structured data sets, has brought on new and complex challenges in the field of data management and analytics. These data sets, usually modeled as large graphs, have attracted both the industry and academia, due to the new opportunities in research and innovation they offer. This situation has also opened the door for new companies to emerge, offering new non-relational and graph-like technologies that are called to play a significant role in upcoming years.

The change in the data paradigm, calls for new benchmarks to test the new emerging technologies, as they set a framework where different systems can compete and compare in a fair way, they let technology providers to identify the bottlenecks and gaps of their systems and, in general, drive the research and development of new information technology solutions. Without them, the uptake of these technologies is at risk by not providing the industry with clear, user-driven targets for performance and functionality.

The LDBC Social Network Benchmark (LDBC-SNB) aims at being comprehensive benchmark setting the rules for the evaluation of graph-like data management technologies. LDBC-SNB is designed to be a plausible look-alike of all the aspects of operating a social network site, as one of the most representative and relevant use case of modern graph-like applications. LDBC-SNB is a work in progress, and initially, it only includes a read only Interactive Workloads, but two more workloads will be introduced in the future: the Business Intelligence and the Analytics. All three workloads will support update queries in future releases. By designing three separate workloads, LDBC-SNB targets a broader range of systems with different nature and characteristics. LDBC-SNB aims at capturing the essential features of these usage scenarios while abstracting away details of specific business deployments.

1.2 Relevance to Industry

LDBC-SNB is intended to provide the following value to different stakeholders:

- For **end users** facing graph processing tasks, LDBC-SNB provides a recognizable scenario against which it is possible to compare merits of different products and technologies. By covering a wide variety of scales and price points, LDBC-SNB can serve as an aid to technology selection.
- For **vendors** of graph database technology, LDBC-SNB provides a checklist of features and performance characteristics that helps in product positioning and can serve to guide new development.
- For **researchers**, both industrial and academic, the LDBC-SNB dataset and workload provide interesting challenges in multiple choke-point areas, such as query optimization, (distributed) graph analysis, transactional throughput, and provides a way to objectively compare the effectiveness and efficiency of new and existing technology in these areas.

The technological scope of the LDBC-SNB comprises all systems that one might conceivably use to perform social network data management tasks:

- **Graph database systems** (e.g. Neo4j, InfiniteGraph, Sparksee, Titan) are novel technologies aimed at storing directed and labeled graphs. They support graph traverals, typically by means of APIs, though some of them also support some sort of graph oriented query language (e.g. Neo4j's Cypher). These systems' internal structures are typically designed to store dynamic graphs that change over time. They oftern support transactional queries with some degree of consistency, and value-based indexes to quicly locate nodes and edges. Finally, their architecture is typically single-machine (non-cluster). These systems can potentially implement the three workloads, though Interactive and Business Intelligence workloads are where they will presumably be more competitive.

- **Graph programming frameworks** (e.g. Giraph, Signal/Collect, Graphlab, Green Marl) are designed to perform global graph queries computations, executed in parallel or lockstep. These computations are typically long latency, involving many nodes and edges and often consist of approximation answers to NP-complete problems. These systems expose an API, sometimes following a vertex centric paradigm, and their architecture targets both single-,machine and cluster systems. Though these systems will likely implement the Graph Analytics workload.

- **RDF database systems** (e.g. OWLIM, Virtuoso, BigData, Jena TDB, Stardog, Allegrograph) are systems that implement the SPARQL1.1 query language, similar in complexity to SQL1992, which allows for structured queries, and simple traversals. RDF database system often come with additional support for simple reasoning (sameAs,subClass), text search and geospatial predicates. RDF database systems generally support transactions, but not always with full concurrency and serializability and their supposed strength is integrating multiple data sources (e.g. DBpedia). Their architecture is both single-machine and clustered, and they will likely target Interactive and Business Intelligence workloads.

- **Relational database systems** (e.g. Postgres, MySQL, Oracle, DB2, SQLserver, Virtuoso, MonetDB, Vectorwise, Vertica, but also Hive and Impala) treat data as relational, and queries are formulated in SQL and/or PL/SQL. Both single-machine and cluster systems exist. They do not normally support recursion, or stateful recursive algorithms, which makes them not at home in the Graph Analytics workloads

- **noSQL database systems** (e.g. key-value stores such as HBase, REDIS, MongoDB, CouchDB, or even MapReduce systems like Hadoop and Pig). are cluster-vbased and scalable. Key-value stores could possibly implement the Interactive Workload, though its navigational aspects would pose some problems as potentially many key-value lookups are needed. MapReduce systems could be suited for the Graph Analytics workload. but their query latency would presumably be so high that the Business Intelligence workload would not make sense, though we note that some of the key-value stores (e.g. MongoDB) provide a MapReduce query functionality on the data that it stores which could make it suited for the Business Intelligence workload.

1.3 General Benchmark Overview

LDBC-SNB aims at being a complete benchmark, designed with the following goals in mind:

- **Rich coverage**. LDBC-SNB is intended to cover most demands encountered in the management of complexly structured data.

- **Modularity**. LDBC-SNB is broken into parts that can be individually addressed. In this manner LDBC-SNB stimulates innovation without imposing an overly high threshold for participation.

- **Reasonable implementation cost**. For a product offering relevant functionality, the effort for obtaining initial results with SNB should be small, on the order of days.

- **Relevant selection of challenges**. Benchmarks are known to direct product development in certain directions. LDBC-SNB is informed by the state of the art in database research so as to offer optimization challenges for years to come while not having a prohibitively high threshold for entry.

- **Reproducibility and documentation of results**. LDBC-SNB will specify the rules for full disclosure of benchmark execution and for auditing of benchmark runs. The workloads may be run on any equipment but the exact configuration and price of the hardware and software must be disclosed.

LDBC-SNB benchmark is modeled around the operation of a real social network site. A social network site represents a relevant use case for the following reasons:

- It is simple to understand for a large audience, as it is arguably present to our every-day life in different shapes and forms.
- It allows testing a complete range of interesting challenges, by means of different workloads targeting systems of different nature and characteristics.
- A social network can be scaled, allowing the design of a scalable benchmark targeting systems of different sizes and budgets.

In Section 2.2, LDBC-SNB defines the schema of the data used in the benchmark. The schema, represents a realistic social network, including people and their activity in the social network during a period of time. Personal information of each person, such as the name, the birth day, interests or the places where people work or study, is included. Persons' activity is represented in the form of friendhisp relationships and content sharing (i.e messages and pictures). LDBC-SNB provides a scalable synthetic data generator based on the MapReduce parallel paradigm, that produces networks with the described schema with distributions and correlations similar to those expected in a real social network. Furthermore, the data generator is designed to be user friendly. The proposed data schema is shared by all the different proposed workloads, those we currently have, and those that will be proposed in the future.

In Section 2.3, the Interactive Workload is proposed. Currently it only defines read queries, but will be updated in the near future to support updates. Two more workloads are planned: Business Intelligence Workload and Analytical workload. Workloads are designed to mimic the different usage scenarios found in operating a real social network site, and each of them targets one or more types of systems. Each workload defines a set of queries and query mixes, designed to stress the SUTs in different choke-point areas, while being credible and realistic. Interactive workload reproduces the interaction between the users of the social network by including lookups and transactions that update small portions of the data base. These queries are designed to be interactive and target systems capable of responding such queries with low latency for multiple concurrent users. Business Intelligence workload, will represent those business intelligence analytics a social network company would like to perform in the social network, in order to take advantage of the data to discover new business opportunities. This workload will explore moderate portions of data from different entities, and performing more resource intensive operations. Finally, the graph analytics workload will aim at exploring the characteristics of the underlying structure of the network. Shortest paths, community detection or centrality, are representative queries of this workload, and will imply touching a vast amount of the dataset.

LDBC-SNB provides an execution test driver, which is responsible of executing the workloads and gathering the results. The driver is designed with simplicity and portability in mind, to ease the implementation on systems with different nature and characteristics, at a low implementation cost. Furthermore, it will automatically handle the validation of the queries in the near future. The overall philosophy of LDBC-SNB is to provide all the necessary software tools to run the benchmark, and therefore to reduce the benchmark's entry point as much as possible.

Detailed instructions to generate the required datasets and to run Interactive Workload of the benchmark, are described in Chapter 3. Finally, in the Appendix, Interactive Workload query implementation examples in Virtuoso's SQL, Virtuoso's SPARQL and Neo4j Cypher are shown.

1.4 Participation of Industry and Academia

The list of institutions that take part in the definition and development of LDBC-SNB is formed by relevant actors from both the industry and academia in the field of linked data management. All the participants have contributed with their experience and expertise in the field, making a credible and relevant benchmark that meets all the desired needs. The list of participants is the following:

- FOUNDATION FOR RESEARCH AND TECHNOLOGY HELLAS
- NEO4J

- ONTOTEXT
- OPENLINK
- TECHNISCHE UNIVERSITAET MUENCHEN
- UNIVERSITAET INNSBRUCK
- UNIVERSITAT POLITECNICA DE CATALUNYA
- VRIJE UNIVERSITEIT AMSTERDAM

Besides the aforementioned institutions, during the development of the benchmark several meetings with the technical and users community have been conducted, receiving an invaluable feedback that has contributed to the whole development of the benchmark in every of its aspects.

2.1 Requirements

LDBC-SNB is designed to be flexible and to have an affordable entry point. From small single node and in memory systems to large distributed multi-node clusters have its own place in LDBC-SNB. Therefore, the requirements to fulfill to execute LDBC-SNB are limited to pure software requirements to be able to run the tools. All the software provided by LDBC-SNB have been developed and tested under Linux, and use the following technologies:

- Oracle Java Development Kit 1.7 or newer.
- Hadoop 1.2.1
- Python 2.7

LDBC-SNB does not impose the usage of any specific type of system, as it targets systems of different nature and characteristics, from graph databases, graph processing frameworks and RDF systems, to traditional relational database management systems. Consequently, any language or API capable of expressing the proposed queries can be used. Similarly, data can be stored in the most convenient manner the test sponsor may decide.

2.2 Data

This section introduces the data used by LDBC-SNB. This includes the different data types, the data schema, how it is generated and the different scale factors.

2.2.1 Data Types

Table 2.1 describes the different types used in the whole benchmark.

Type	Description
ID	integer type with 64-bit precision. All IDs within a single entity, are unique
32-bit Integer	integer type with 32-bit precision
64-bit Integer	integer type with 64-bit precision
String	variable length text of size 40
Text	variable length text of size 2000
Date	date with a precision of a day
DateTime	date with a precision of a second

Table 2.1: Description of the data types.

2.2.2 Data Schema

Figure 2.1 shows the data schema in UML. The schema defines the structure of the data used in the benchmark in terms of entities and their relations. Data represents a snapshot of the activity of a social network during a period of time. Data includes entities such as Persons, Organizations, and Places. The schema also models the way persons interact, by means of the friendship relations established with other persons, and the sharing of content such as messages (both textual and images), replies to messages and likes to messages. People form groups to talk about specific topics, which are represented as tags.

LDBC-SNB has been designed to be flexible and to target systems of different nature and characteristics. As such, it does not force any particular internal representation of the schema. The DATAGEN described in Section 3.1 supports multiple output data formats to fit the needs of different types of systems, including RDF, relational DBMS and graph DBMS.

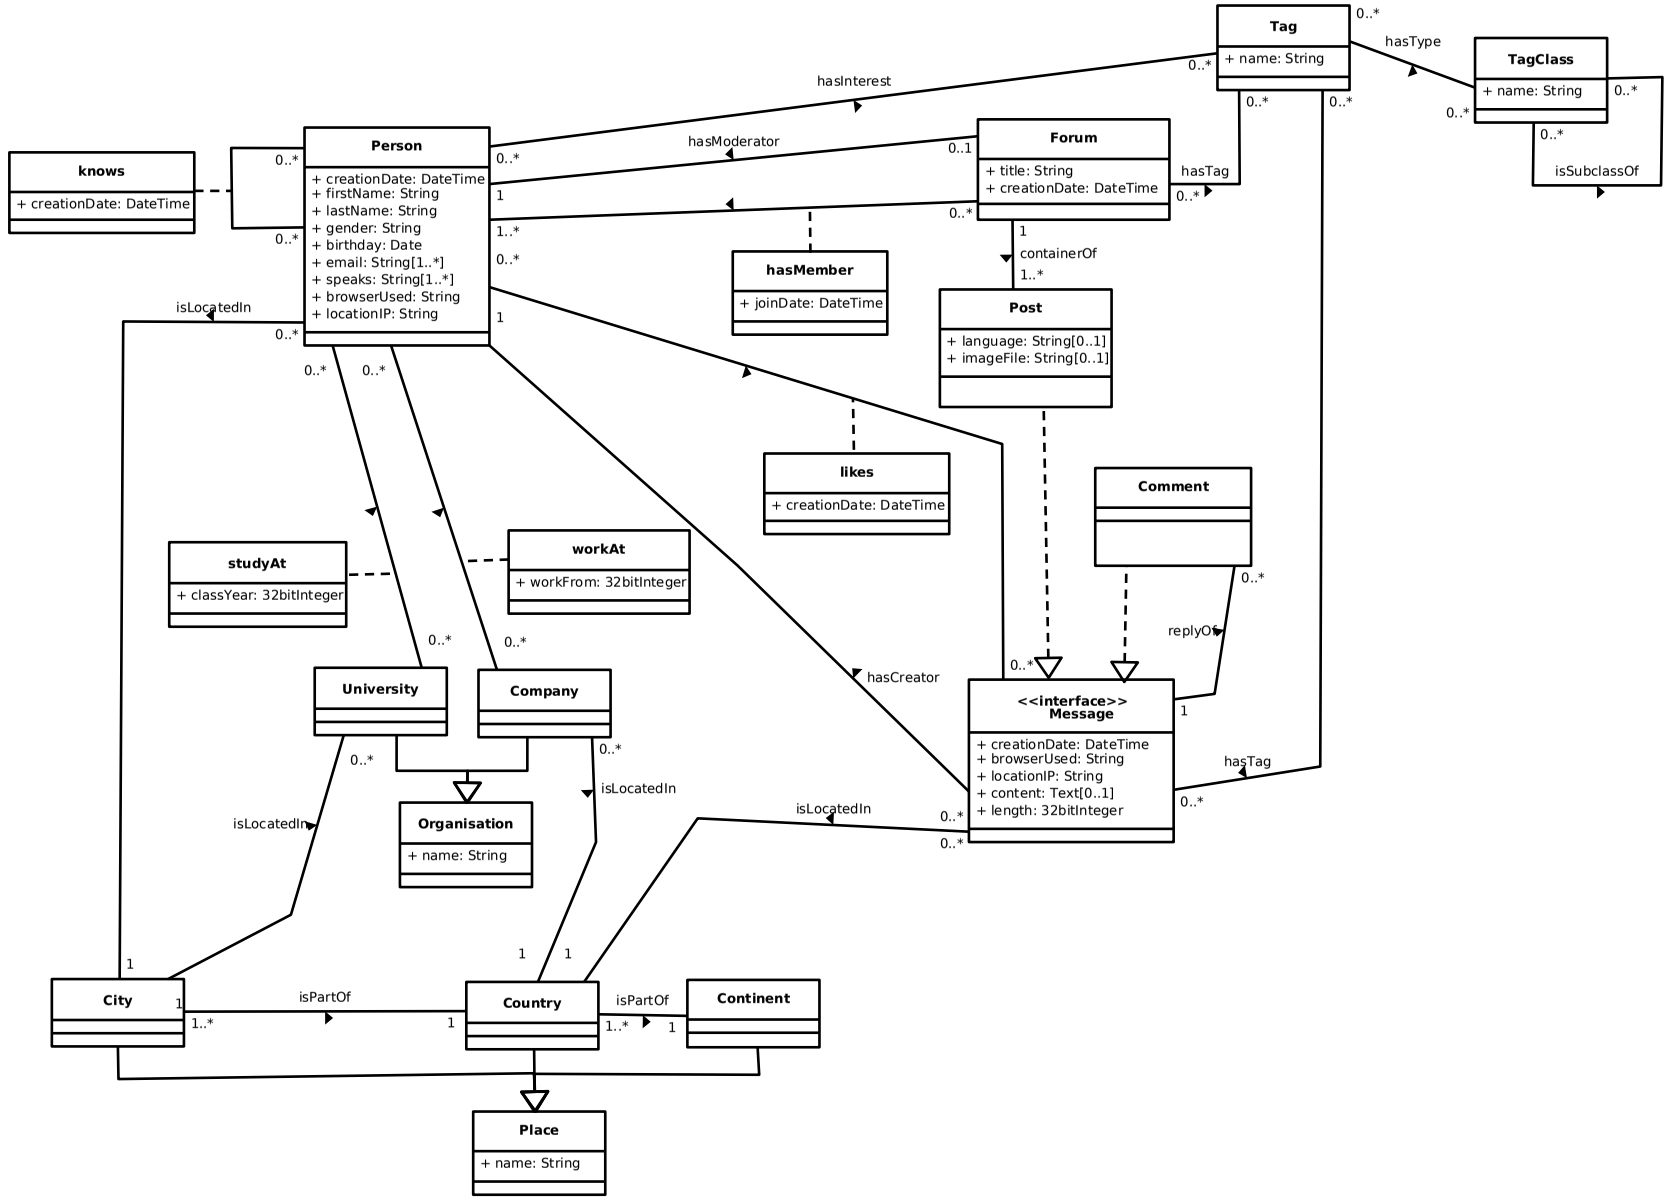

Figure 2.1: The LDBC-SNB data schema

The schema specifies different entities, their attributes and their relations. All of them are described in the following sections.

Textual Restrictions

- Posts have content or imageFile. They have one of them but not both. The one they do not have is an empty string.

Entities

City: a sub-class of a Place, and represents a city of the real world. City entities are used to specify where persons live, as well as where universities operate.

Comment: a sub-class of a Message, and represents a comment made by a person to an existing message (either a Post or a Comment).

Company: a sub-class of an Organization, and represents a company where persons work.

Country: a sub-class of a Place, and represents a continent of the real world.

Forum: a meeting point where people post messages. Forums are characterized by the topics (represented as tags) people in the forum are talking about. Although from the schema's perspective it is not evident, there exist three different types of forums: persons' personal walls, image albums, and groups. They are distinguished by their titles. Table 2.2 shows the attributes of Forum entity.

Attribute	Type	Description
id	ID	The identifier of the forum.
title	String	The title of the forum.
creationDate	DateTime	The date the forum was created

Table 2.2: Attributes of Forum entity.

Message: an abstract entity that represents a message created by a person. Table 2.3 shows the attributes of Message abstract entity.

Attribute	Type	Description
id	ID	The identifier of the message.
browserUsed	String	The browser used by the Person to create the message.
creationDate	DateTime	The date the message was created.
locationIP	String	The IP of the location from which the message was created.
content	Text[0..1]	The content of the message.
length	32bitInteger	The length of the content.

Table 2.3: Attributes of Message interface.

Organization: an institution of the real world. Table 2.4 shows the attributes of Organization entity.

Attribute	Type	Description
id	ID	The identifier of the organization.
name	String	The name of the organization.

Table 2.4: Attributes of Organization entity.

Person: the avatar a real world person creates when he/she joins the network, and contains various information about the person as well as network related information. Table 2.5 shows the attributes of Person entity.

Attribute	Type	Description
id	ID	The identifier of the person.
firstName	String	The first name of the person.
lastName	String	The last name of the person.
gender	String	The gender of the person.
birthDay	Date	The birthday of the person .
email	String[1..*]	The set of emails the person has.
speaks	String[1..*]	The set of languages the person speaks.
browserUser	String	The browser used by the person when he/she registered to the social network.
locationIp	String	The IP of the location from which the person was registered to the social network.
creationDate	DateTime	The date the person joined the social network.

Table 2.5: Attributes of Person entity.

Place: a place in the world. Table 2.6 shows the attributes of Place entity.

Attribute	Type	Description
id	ID	The identifier of the place.
name	String	The name of the place.

Table 2.6: Attributes of Place entity.

Post: a sub-class of Message, that is posted in a forum. Posts are created by persons into the forums where they belong. Posts contain either content or imageFile, always one of them but never both. The one they do not have is an empty string. Table 2.7 shows the attributes of Post entity.

Attribute	Type	Description
language	String[0..1]	The language of the post.
imageFile	String[0..1]	The image file of the post..

Table 2.7: Attributes of Post entity.

Tag: a topic or a concept. Tags are used to specify the topics of forums and posts, as well as the topics a person is interested in. Table 2.8 shows the attributes of Tag entity.

Attribute	Type	Description
id	ID	The identifier of the tag.
name	String	The name of the tag.

Table 2.8: Attributes of Tag entity.

TagClass: a class or a category used to build a hierarchy of tags. Table 2.9 shows the attributes of TagClass entity.

Attribute	Type	Description
id	ID	The identifier of the tagclass.
name	String	The name of the tagclass.

Table 2.9: Attributes of TagClass entity.

University: a sub-class of Organization, and represents an institution where persons study.

Relations

Relations connect entities of different types. Entities are defined by their ”id” attribute.

Name	Tail	Head	Type	Description
containerOf	Forum[1]	Post[1..*]	D	A Forum and a Post contained in it
hasCreator	Message[0..*]	Person[1]	D	A Message and its creator (Person)
hasInterest	Person[0..*]	Tag[0..*]	D	A Person and a Tag representing a topic the person is interested in
hasMember	Forum[0..*]	Person[1..*]	D	A Forum and a member (Person) of the forum • **Attribute**: joinDate • **Type:** DateTime • **Description:** The Date the person joined the forum
hasModerator	Forum[0..*]	Person[1]	D	A Forum and its moderator (Person)
hasTag	Message[0..*]	Tag[0..*]	D	A Message and a Tag representing the message’s topic
hasTag	Forum[0..*]	Tag[0..*]	D	A Forum and a Tag representing the forum’s topic
hasType	Tag[0..*]	TagClass[0..*]	D	A Tag and a TagClass the tag belongs to
isLocatedIn	Company[0..*]	Country[1]	D	A Company and its home Country
isLocatedIn	Message[0..*]	Country[1]	D	A Message and the Country from which it was issued
isLocatedIn	Person[0..*]	City[1]	D	A Person and their home City
isLocatedIn	University[0..*]	City[1]	D	A University and the City where the university is
isPartOf	City[1..*]	Country[1]	D	A City and the Country it is part of
isPartOf	Country[1..*]	Continent[1]	D	A Country and the Continent it is part of
isSubclassOf	TagClass[0..*]	TagClass[0..*]	D	A TagClass its parent TagClass
knows	Person[0..*]	Person[0..*]	U	Two Persons that know each other • **Attribute**: creationDate • **Type:** DateTime • **Description:** The date the knows relation was established
likes	Person[0..*]	Message[0..*]	D	A Person that likes a Message • **Attribute**: creationDate • **Type:** DateTime • **Description:** The date the like was issued
replyOf	Comment[0..*]	Message[1]	D	A Comment and the Message it replies

studyAt	Person[0..*]	University[0..*]	D	A Person and a University it has studied • **Attribute**: classYear • **Type:** 32-bit Integer • **Description:** The year the person graduated.
workAt	Person[0..*]	Company[0..*]	D	A Person and a Company it works • **Attribute**: workFrom • **Type:** 32-bit Integer • **Description:** The year the person started to work at that company

Table 2.10: Description of the data relations.

2.2.3 Data Generation

LDBC-SNB provides DATAGEN (Data Base Generator), which produces synthetic datasets following the schema described above. Data produced mimics a social network's activity during a period of time. Three parameters determine the generated data: the number of persons, the number of years simulated, and the starting year of simulation. DATAGEN is defined by the following characteristics:

- **Realism.** Data generated by DATAGEN mimics the characteristics of those found in a real social network. In DATAGEN, output attributes, cardinalities, correlations and distributions have been finely tuned to reproduce a real social network in each of its aspects On the one hand, it is aware of the data and link distributions found in a real social network such as Facebook. On the other hand, it uses real data from DBPedia, such as property dictionaries, which are used to ensure that attribute values are realistic and correlated.
- **Scalability.** Since LDBC-SNB targets systems of different scales and budgets, DATAGEN is capable of generating datasets of different sizes, from a few Gigabytes to Terabytes. DATAGEN is implemented following the MapReduce parallel paradigm, allowing the generation of small datasets in single node machines, as well as large datasets on commodity clusters.
- **Determinism.** DATAGEN is deterministic regardless of the number of cores/machines used to produce the data. This important feature guarantees that all Test Sponsors will face the same dataset, thus, making the comparisons between different systems fair and the benchmarks' results reproducible.
- **Usability.** LDBC-SNB is designed to have an affordable entry point. As such, DATAGEN's design is severely influenced by this philosophy, and therefore it is designed to be as easy to use as possible.

Resource Files

DATAGEN uses a set of resource files with data extracted from DBpedia. Conceptually, DATAGEN generates attribute's values following a property dictionary model that is defined by

- a dictionary D
- a ranking function R
- a probability function F

Dictionary D is a fixed set of values. The ranking function R is a bijection that assigns to each value in a dictionary a unique rank between 1 and $|D|$. The probability density function F specifies how the data generator chooses values from dictionary D using the rank for each term in the dictionary. The idea to have a separate ranking and probability function is motivated by the need of generating correlated values: in particular, the ranking function is typically parameterized by some parameters: different parameter values result in different rankings. For example, in the case of a dictionary of property firstName, the popularity of first names, might depend on the gender, country and birthDate properties. Thus, the fact that the popularity of first names in different countries and times is different, is reflected by the different ranks produced by function R over the full dictionary of names. DATAGEN uses a dictionary for each literal property, as well as ranking functions for all literal properties. These are materialized in a set of resource files, which are described in Table 2.11.

Resource Name	**Description**
Browsers	Contains a list of web browsers and their probability to be used. It is used to set the browsers used by the users.
Cities by Country	Contains a list of cites and the country they belong. It is used to assign cities to users and universities.
Companies by Country	Contains the set of companies per country. It is used to set the countries where companies operate.
Countries	Contains a list of countries and their populations. It is used to obtain the amount of people generated for each country.
Emails	Contains the set of email providers. It is used to generate the email accounts of persons.
IP Zones	Contains the set of IP ranges assigned to each country. It is used to assign the IP addresses to users.
Languages by Country	Contains the set of languages spoken in each country. It is used to set the languages spoken by each user.
Name by Country	Contains the set of names and the probability to appear in each country. It is used to assign names to persons, correlated with their countries.
Popular places by Country	Contains the set of popular places per country. These are used to set where images attached to posts are taken from.
Surnames' by Country	Contains the set of surnames and the probability to appear in each country. It is used to assign surnames to persons, correlated with their countries.
Tags by Country	Contains a set of tags and their probability to appear in each country. It is used to assign the interests to persons and forums.
Tag Classes	Contains, for each tag, the classes it belongs to.
Tag Hierarchies	Contains, for each tagClass, their parent tagClass.
Tag Matrix	Contains, for each tag, the correlation probability with the other tags. It is used enrich the tags associated to messages.
Tag Text	Contains, for each tag, a text. This is used to generate the text for messages.
Universities by City	Contains the set of universities per city. It is used to set the cities where universities operate.

Table 2.11: Resource files

Graph Generation

Figure 2.2 conceptually depicts the full data generation process. The first step loads all the dictionaries and resource files, and initializes the DATAGEN parameters. Second, it generates all the Persons in the graph, and the minimum necessary information to operate. Part of these information are the interests of the persons, and the number of knows relationships of every person, which is guided by a degree distribution function similar to that found in Facebook [4].

The next three steps are devoted to the creation of knows relationships. An important aspect of real social networks, is the fact that similar persons (with similar interests and behaviors) tend to be connected. This is known as the Homophily principle [3], and implies the presence of a larger amount of triangles than that expected in a random network. In order to reproduce this characteristic, DATAGEN generates the edges by means of correlation dimensions. Given a person, the probability to be connected to another person is typically skewed with respect to some similarity between the persons. That is, for a person n and for a small set of persons that are somehow similar to it, there is a high connectivity probability, whereas for most other persons, this probability is quite low. This knowledge is exploited by DATAGEN to reproduce correlations.

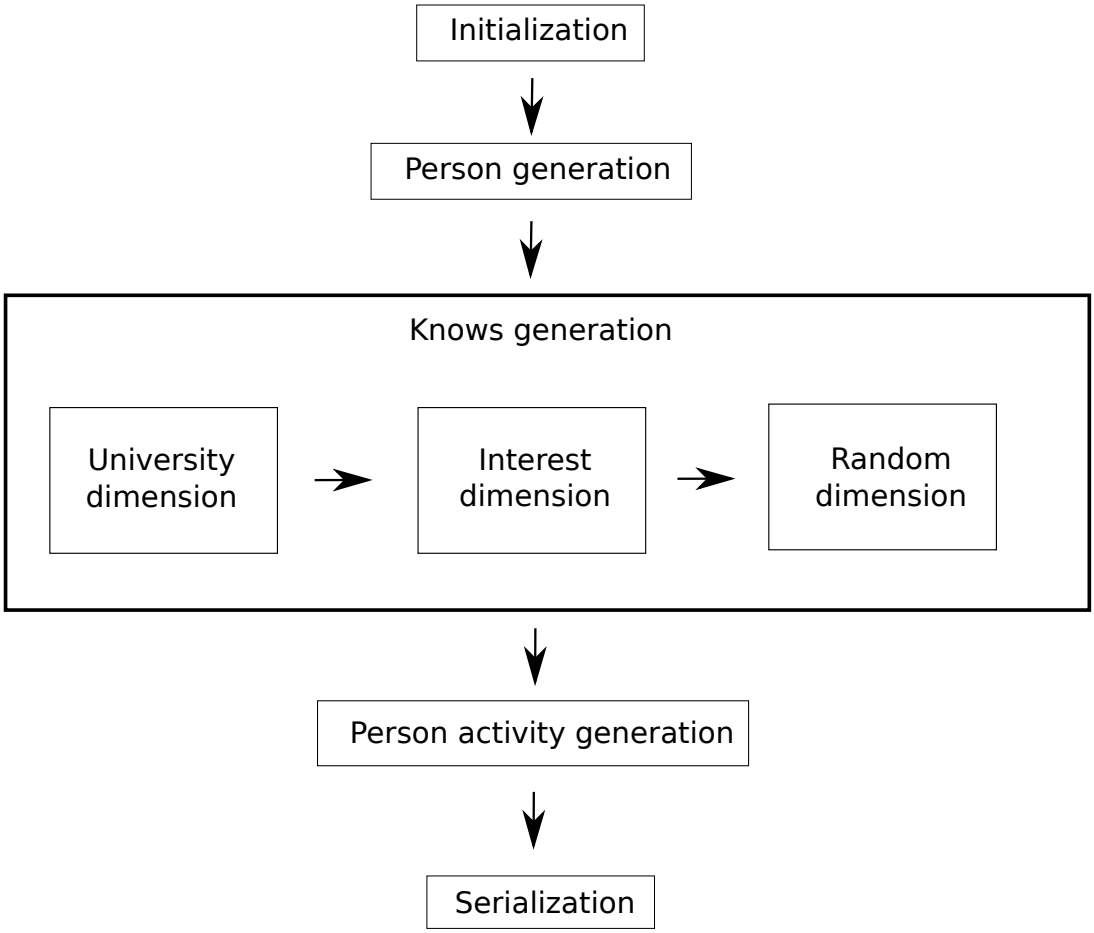

Figure 2.2: The DATAGEN generation process.

Given a similarity function $M(x) : n[0, \infty]$ that gives a score to a person, with the characteristic that two similar persons will have similar scores, we can sort all the persons by function M and compare a person n against only the W neighboring persons in the sorted array. The consequence of this approach is that similar persons are grouped together, and the larger the distance between two persons indicates a monotonic increase in their similarity difference. In order to choose the persons to connect, DATAGEN uses a geometric probability distribution that provides a probability for picking persons to connect, that are between 1 and W positions apart in the similarity ranking.
Similarity functions and probability distribution functions over ranked distance drive what kind of persons will be connected with an edge, not how many. As stated above, the number of friends of a person is determined by a Facebook-like distribution. The edges that will be connected to a person n, are selected by randomly picking the required number of edges according to the correlated probability distributions as discussed before. In the case that multiple correlations exist, another probability function is used to divide the intended number of

edges between the various correlation dimensions. In DATAGEN, three correlated dimensions are chosen: the first one depends on where the person studied and when, and the second correlation dimension depends on the interests of the person, and the third one is random (to reproduce the random noise present in real data). Thus, DATAGEN has a Facebook-like distributed node degree, and a predictable (but not fixed) average split between the reasons for creating edges.
In the next step, person's activity, in the form of forums, posts and comments is created. DATAGEN reproduces the fact that people with a larger number of friends have a higher activity, and hence post more photos and comments to a larger number of posts. Another important characteristic of real users' activity in social network, are time correlations. Usually, users' posts creation in a social network is driven by real world events. For instance, one may think about an important event such as the elections in a country, or a natural disaster. Around the time these events occur, network activity about these events' topics sees an increase in volume. DATAGEN reproduces these characteristics with the simulation of what we name as flashmob events. Several events are generated randomly at the beginning of the generation process, which are assigned a random tag, and are given a time and an intensity which represents the repercussion of the event in the real world. When persons' posts are created, some of them are classified as flashmob posts, and their topics and dates are assigned based on the generated flashmob events. The volume of activity around this events is modeled following a model similar to that described in [2]. Furthermore, in order to reproduce the more uniform every day's user activity, DATAGEN also generates post uniformly distributed along all the simulated time.
Finally, in the last step the data is serialized into the output files.

Implementation Details

DATAGEN is implemented using the MapReduce parallel paradigm. In MapReduce, a Map function runs on different parts of the input data, in parallel and on many node clusters. This function processes the input data and produces for each result a key. Reduce functions then obtain this data and Reducers run in parallel on many cluster nodes. The produced key simply determines the Reducer to which the results are sent. The use of the MapReduce paradigm allows the generator to scale considerably, allowing the generation of huge datasets by using clusters of machines.
In the case of DATAGEN, the overall process is divided into three MapReduce jobs. In the first job, each mapper generates a subset of the persons of the graph. A key is assigned to each person using one of the similarity functions described above. Then, reducers receive the the key-value pairs sorted by the key, generate the knows relations following the described windowing process, and assign to each person a new key based on another similarity function, for the next MapReduce pass. This process can be successively repeated for additional correlation dimension. Finally, the last reducer generates the remaining information such as forums, posts and comments.

Data Output

DATAGEN is built to split the simulated social network into two parts: the static part and the update stream part. The static part contains the data that will be bulk loaded by the Test Sponsor's system and is formatted in one of the supported formats: CSV, CSV_MERGE_FOREIGN and TTL. In addition to the network data, a stream of reads is also produced, which is used by the test driver to execute the queries. A detailed description of each supported format and the generated files is described in Section 3.1.2. For a description of how the read stream is generated, please refer to Section 2.3.1. The update streams part contains update events to the network, consisting in insertions of data, and is also used by the test driver to issue updates.
What percentage of the network is output as static, and what percentage is output as updates, can be configured and depends on the needs of the workload. To compute what data goes to each of the parts, a point or threshold in the simulated time line is computed. All entities that fall before the threshold, go to the static part. All entities falling after the threshold, are output as update streams. Consequently, if a relation contains one of the entities falling into the update stream, then the relation is also output as an update.
As currently the only supported workload is the Interactive Workload with only lookups, DATAGEN is configured to output the entire 100% of the network as static by default.

2.2.4 Scale Factors

LDBC-SNB defines a set of scale factors (SFs), targeting systems of different sizes and budgets. SFs are computed based on the ASCII size in Gigabytes of the generated output files using the CSV serializer. For example, SF 1 weights roughly 1GB in CSV format, SF 3 weights roughly 3GB and so on and so forth. The proposed SFs are the following: 1, 3, 10, 30, 100, 300, 1000. The Test Sponsor may select the SF that better fits their needs, by properly configuring the DATAGEN, as described in Section 3.1.
The size of the resulting dataset, is mainly affected by the following configuration parameters: the number of persons and the number of years simulated. Different SFs are computed by scaling the number of Persons in the network, while fixing the number of years simulated. Table 2.12 shows the parameters used in each of the SFs.

Scale Factor	1	3	10	30	100	300	1000
# of Persons	11K	27K	73K	182K	499K	1.25M	3.6M
# of Years	3	3	3	3	3	3	3
Start Year	2010	2010	2010	2010	2010	2010	2010

Table 2.12: Parameters of each scale factor.

For example, SF 30 consists of the activity of a social network of 182K users during a period of three years, starting from 2010. In Appendix B.1, we show the statistics of each of the proposed SFs in detail, including distributions for some of the relations.

2.3 Workloads

2.3.1 Interactive Workload

Choke Points

The design of the interactive workload queries has been conceived around two main aspects: realism and technological relevance. While realism has been assessed by looking at existing social networks and thinking about what interesting functionalities a user might desire from them, technological relevance has been achieved by identifying a set of choke points queries should stress. These choke points capture those critical operations, techniques or technologies that could significatively affect the performance of the queries. The choke points can be summarized in the following list:

- **Aggregation Performance.**

  The queries generally have a top k order by and often a group by in addition to this. These offer multiple optimization opportunities. The queries also often have distinct operators, i.e. distinct friends within two steps. Collectively these are all set operations that may be implemented with some combination of hash and sorting, possibly exploiting ordering in the data itself. The aggregates are not limited to counts and sums. For example string concatenation occurs as an aggregate, testing possible user defined aggregate support. There is a wide range of cardinalities in grouping, from low, e.g. country, to high, e.g. post.

- **Join Performance.**

  Each graph traversal step is in principle a join. The join patterns are diverse, exercising both index and hash based operators. Queries are designed so as to reward judicious use of hash join by having patterns starting with one entity, fetching many related entities and then testing how these are related to a third entity, e.g. posts of a user with a tag of a given type.

- **Data Access Locality.**

  Graph problems are notoriously non-local. However, when queries touch any non-trivial fraction of a dataset, locality will emerge and can be exploited, for example by vectored index access or by ordering data so that that a merge join is possible.

- **Expression Calculation.**

  Queries often have expressions, including conditional expressions. This provides opportunities for vectoring and tests efficient management of intermediate results.

- **Correlated Subqueries.**

  The workload has many correlated subqueries, for example constructts like x within two steps but not in one step, which would typically be a correlated subquery with NOT EXISTS. There are also scalar subqueries with aggregation, for example returning the count of posts satisfying a certain criteria.

- **Parallelism and Concurrency.**

  All queries offer opportunities for parallelism. This tests a wide range of constructs, for example partitioned parallel variants of group by and distinct. An interactive workload will typically avoid trivially parallelizable table scans. Thus the opportunities that exist must be captured by index based, navigational query plans. The choice of whether to parallelize or not is often left to run time and will have to depend on the actual data seen in the execution, as starting a parallel thread with too little to do is counter-productive.

- **Graph Specifics.**

  Graph problems are generally characterized by transitive properties and the fact that neighboring vertices often have a large overlap in their environments. This makes cardinality estimation harder. For example, a query optimizer needs to recognize whether a relationship has a tree or graph shape in order to make correct cardinality estimations. Further, there are problems aggregating properties over a set of consecutive edges. The workload contains business questions dealing with paths and aggregates across paths, as well as the easier case of determining a membership in a hierarchy with a transitive part-of relation.

Query Description Format

Queries are described in natural language using a well-defined structure that consists of three sections: *description*, a concise textual description of the query; *parameters*, a list of input parameters and their types; and *results*, a list of expected results and their types. The syntax used in *parameters* and *results* sections is as follows:

- **Entity**: entity type in the dataset.
  One word, possibly constructed by appending multiple words together, starting with uppercase character and following the camel case notation, e.g. `TagClass` represents an entity of type "TagClass".
- **Relationship**: relationship type in the dataset.
  One word, possibly constructed by appending multiple words together, starting with lowercase character and following the camel case notation, and surrounded by arrow to communicate direction, e.g. `-worksAt->` represents a directed relationship of type "worksAt".
- **Attribute**: attribute of an entity or relationship in the dataset.
  One word, possibly constructed by appending multiple words together, starting with lowercase character and following the camel case notation, and prefixed by a "." to dereference the entity/relationship, e.g. `Person.firstName` refers to "firstName" attribute on the "Person" entity, and `-studyAt->.classYear` refers to "classYear" attribute on the "studyAt" relationship.
- **Unordered Set**: an unordered collection of distinct elements.
  Surrounded by { and } braces, with the element type between them, e.g. `{String}` refers to a set of strings.
- **Ordered List**: an ordered collection where duplicate elements are allowed.
  Surrounded by [and] braces, with the element type between them, e.g. `[String]` refers to a list of strings.
- **Ordered Tuple**: a fixed length, fixed order list of elements, where elements at each position of the tuple have predefined, possibly different, types.

Surrounded by < and > braces, with the element types between them in a specific order e.g. `<String, Boolean>` refers to a 2-tuple containing a string value in the first element and a boolean value in the second, and `[<String, Boolean>]` is an ordered list of those 2-tuples.

Lookup Query Descriptions

Notes:

- Some queries require returning the content of a post. As stated in the schema, posts have content or imageFile, but not both. An empty string in content represents the post not having content, therefore, it must have a non empty string in imageFile and the other way around.

1. Friends with certain name

   - **Description:** Given a start Person, find up to 20 Persons with a given first name that the start Person is connected to (excluding start Person) by at most 3 steps via Knows relationships. Return Persons, including summaries of the Persons workplaces and places of study. Sort results ascending by their distance from the start Person, for Persons within the same distance sort ascending by their last name, and for Persons with same last name ascending by their identifier
   - **Parameters:**

Person.id	ID
Person.firstName	String

   - **Results:**

Person.id	ID
Person.lastName	String
Person.birthday	Date
Person.creationDate	DateTime
Person.gender	String
Person.browserUsed	String
Person.locationIP	String
{Person.emails}	{String}
{Person.language}	{String}
Person-isLocatedIn->Place.name	String
{Person-studyAt->University.name, Person-studyAt->.classYear, Person-studyAt->University-isLocatedIn->City.name}	{<String, 32-bit Integer, String>}
{Person-workAt->Company.name, Person-workAt->.workFrom, Person-workAt->Company-isLocatedIn->Country.name}	{<String, 32-bit Integer, String>}

2. Recent posts and comments by your friends

   - **Description:** Given a start Person, find (most recent) Posts and Comments from all of that Person's friends, that were created before (and including) a given date. Return the top 20 Posts/Comments, and the Person that created each of them. Sort results descending by creation date, and then ascending by Post identifier.
   - **Parameters:**

Person.id	ID
date	DateTime

   - **Results:**

Person.id	ID
Person.firstName	String
Person.lastName	String
Post.id/Comment.id	ID
Post.content/Post.imageFile/Comment.content	String
Post.creationDate/Comment.creationDate	DateTime

3. Friends and friends of friends that have been to countries X and Y

- **Description:** Given a start Person, find Persons that are their friends and friends of friends (excluding start Person) that have made Posts/Comments in the given Countries X and Y within a given period. Only Persons that are foreign to Countries X and Y are considered, that is Persons whose Location is not Country X or Country Y. Return top 20 Persons, and their Post/Comment counts, in the given countries and period. Sort results descending by total number of Posts/Comments, and then ascending by Person identifier.
- **Parameters:**

Person.id	ID	
CountryX.name	String	
CountryY.name	String	
startDate	Date	// beginning of requested period
duration	32-bit Integer	// duration of requested period, in days // the interval [startDate, startDate + Duration) is closed-open

- **Results:**

Person.id	ID	
Person.firstName	String	
Person.lastName	String	
countx	32-bit Integer	// number of Posts/Comments from Country X made by Person within the given time
county	32-bit Integer	// number of Posts/Comments from Country Y made by Person within the given time
count	32-bit Integer	// countx + county

4. New topics
   - **Description:** Given a start Person, find Tags that are attached to Posts that were created by that Person's friends. Only include Tags that were attached to Posts created within a given time interval, and that were never attached to Posts created before this interval. Return top 10 Tags, and the count of Posts, which were created within the given time interval, that this Tag was attached to. Sort results descending by Post count, and then ascending by Tag name.
   - **Parameters:**

Person.id	ID	
startDate	Date	
duration	32-bit Integer	// duration of requested period, in days // the interval [startDate, startDate + Duration) is closed-open

   - **Results:**

Tag.name	String	
count	32-bit Integer	// number of Posts made within the given time interval that have this Tag

5. New groups
   - **Description:** Given a start Person, find the Forums which that PersonâĂŹs friends and friends of friends (excluding start Person) became Members of after a given date. Return top 20 Forums, and the number of Posts in each Forum that was Created by any of these Persons. For each Forum consider only those Persons which joined that particular Forum after the given date. Sort results descending by the count of Posts, and then ascending by Forum identifier
   - **Parameters:**

Person.id	ID	
date	Date	

   - **Results:**

Forum.title	String	
count	32-bit Integer	// number of Posts made in Forum that were created by friends

6. Tag co-occurrence
   - **Description:** Given a start Person and some Tag, find the other Tags that occur together with this Tag on Posts that were created by start Person's friends and friends of friends (excluding start Person). Return top 10 Tags, and the count of Posts that were created by these Persons, which contain both this Tag and the given Tag. Sort results descending by count, and then ascending by Tag name.

- **Parameters:**

Person.id	ID
Tag.name	String

- **Results:**

Tag.name	String	
count	32-bit Integer	// number of Posts that were created by friends and friends of friends, which contain this Tag

7. Recent likes

- **Description:** Given a start Person, find (most recent) Likes on any of start Person's Posts/Comments. Return top 20 Persons that Liked any of start Person's Posts/Comments, the Post/Comment they liked most recently, creation date of that Like, and the latency (in minutes) between creation of Post/Comment and Like. Additionally, return a flag indicating whether the liker is a friend of start Person. In the case that a Person Liked multiple Posts/Comments at the same time, return the Post/Comment with lowest identifier. Sort results descending by creation time of Like, then ascending by Person identifier of liker.
- **Parameters:**

Person.id	64-bit Integer

- **Results:**

Person.id	ID	
Person.firstName	String	
Person.lastName	String	
Like.creationDate	DateTime	
Post.id/Comment.id	ID	
Post.content/Post.imageFile/Comment.content	String	
latency	32-bit Integer	// duration between creation of Post/Comment and Like, in minutes
isNew	Boolean	// false if liker Person is friend of start Person, true otherwise

8. Recent replies

- **Description:** Given a start Person, find (most recent) Comments that are replies to Posts/Comments of the start Person. Only consider immediate (1-hop) replies, not the transitive (multi-hop) case. Return the top 20 reply Comments, and the Person that created each reply Comment. Sort results descending by creation date of reply Comment, and then ascending by identifier of reply Comment.
- **Parameters:**

Person.id	ID

- **Results:**

Person.id	ID
Person.firstName	String
Person.lastName	String
Comment.creationDate	DateTime
Comment.id	ID
Comment.content	String

9. Recent posts and comments by friends or friends of friends

- **Description:** Given a start Person, find the (most recent) Posts/Comments created by that Person's friends or friends of friends (excluding start Person). Only consider the Posts/Comments created before a given date (excluding that date). Return the top 20 Posts/Comments, and the Person that created each of those Posts/Comments. Sort results descending by creation date of Post/Comment, and then ascending by Post/Comment identifier.
- **Parameters:**

Person.id	ID
date	Date

- **Results:**

Person.id	ID
Person.firstName	String
Person.lastName	String
Post.id/Comment.id	ID
Post.content/Post.imageFile/Comment.content	String
Post.creationDate/Comment.creationDate	DateTime

10. Friend recommendation

    - **Description:** Given a start Person, find that Person's friends of friends (excluding start Person, and immediate friends), who were born on or after the 21st of a given month (in any year) and before the 22nd of the following month. Calculate the similarity between each of these Persons and start Person, where similarity for any Person is defined as follows:
      - common = number of Posts created by that Person, such that the Post has a Tag that start Person is Interested in
      - uncommon = number of Posts created by that Person, such that the Post has no Tag that start Person is Interested in
      - similarity = common - uncommon

      Return top 10 Persons, their Place, and their similarity score. Sort results descending by similarity score, and then ascending by Person identifier
    - **Parameters:**

Person.id	ID	
month	32-bit Integer	// between 1-12

    - **Results:**

Person.id	ID
Person.firstName	String
Person.lastName	String
Person.gender	String
Person-isLocatedIn->Place.name	Sting
similarity	32-bit Integer

11. Job referral

    - **Description:** Given a start Person, find that Person's friends and friends of friends (excluding start Person) who started Working in some Company in a given Country, before a given date (year). Return top 10 Persons, the Company they worked at, and the year they started working at that Company. Sort results ascending by the start date, then ascending by Person identifier, and lastly by Organization name descending.
    - **Parameters:**

Person.id	ID
Country.name	String
year	32-bit Integer

    - **Results:**

Person.id	ID
Person.firstName	String
Person.lastName	String
Person-worksAt->.worksFrom	32-bit Integer
Person-worksAt->Organization.name	String

12. Expert search

    - **Description:** Given a start Person, find the Comments that this Person's friends made in reply to Posts, considering only those Comments that are immediate (1-hop) replies to Posts, not the transitive (multi-hop) case. Only consider Posts with a Tag in a given TagClass or in a descendent of that TagClass. Count the number of these reply Comments, and collect the Tags that were attached to the Posts they replied to. Return top 20 Persons, the reply count, and the collection of Tags. Sort results descending by Comment count, and then ascending by Person identifier
    - **Parameters:**

Person.id	ID
TagClass.id	ID

- **Results:**
  Person.id ID
  Person.firstName String
  Person.lastName String
  {Tag.name} {String}
  count 32-bit Integer // number of reply Comments

13. Single shortest path

    - **Description:** Given two Persons, find the shortest path between these two Persons in the subgraph induced by the Knows relationships. Return the length of this path.
      - -1 : no path found
      - 0: start person = end person
      - > 0: regular case
    - **Parameters:**
      Person.id ID // person 1
      Person.id ID // person 2
    - **Results:**
      length 32-bit Integer

14. Weighted/unweighted paths

    - **Description:** Given two Persons, find all (unweighted) shortest paths between these two Persons, in the subgraph induced by the Knows relationship. Then, for each path calculate a weight. The nodes in the path are Persons, and the weight of a path is the sum of weights between every pair of consecutive Person nodes in the path. The weight for a pair of Persons is calculated such that every reply (by one of the Persons) to a Post (by the other Person) contributes 1.0, and every reply (by ones of the Persons) to a Comment (by the other Person) contributes 0.5. Return all the paths with shortest length, and their weights. Sort results descending by path weight. The order of paths with the same weight is unspecified.
    - **Parameters:**
      Person.id ID // person 1
      Person.id ID // person 2
    - **Results:**
      [Person.id] [ID] // Identifiers representing an ordered sequence of the Persons in the path
      weight 64-bit Float

Substitution parameters

Together with the dataset, DBGEN produces a set of parameters per query type. Parameter generation is designed in such a way that for each query type, all of the generated parameters yield similar runtime behaviour of that query.
Specifically, the selection of parameters for a query template guarantees the following properties of the resulting queries:

P1: the query runtime has a bounded variance: the average runtime corresponds to the behavior of the majority of the queries

P2: the runtime distribution is stable: different samples of (e.g., 10) parameter bindings used in different query streams result in an identical runtime distribution across streams

P3: the optimal logical plan (optimal operator order) of the queries is the same: this ensures that a specific query template tests the system's behavior under the well-chosen technical difficulty (e.g., handling voluminous joins or proper cardinality estimation for subqueries etc.)

As a result, the amount of data that the query touches is roughly the same for every parameter binding, assuming that the query optimizer figures out a reasonable execution plan for the query. This is done to avoid bindings that cause unexpectedly long or short runtimes of queries, or even result in a completely different

optimal execution plan. Such effects could arise due to the data skew and correlations between values in the generated dataset.
In order to get the parameter bindings for each of the queries, we have designed a *Parameter Curation* procedure that works in two stages:

1. for each query template for all possible parameter bindings, we determine the size of intermediate results in the *intended* query plan. Intermediate result size heavily influences the runtime of a query, so two queries with the same operator tree and similar intermediate result sizes at every level of this operator tree are expected to have similar runtimes. This analysis is effectively a side effect of data generation, that is we keep all the necessary counts (number of friends per user, number of posts of friends etc.) as we create the dataset.

2. then, a greedy algorithm selects ("curates") those parameters with similar intermediate result counts from the domain of all the parameters.

Parameter bindings are stored in the `substitution_parameters` folder inside the data generator directory. Each query gets its bindings in a separate file. Every line of a parameter file is a JSON-formatted collection of key-value pairs (name of the parameter and its value). For example, the Query 1 parameter bindings are stored in file `query_1_param.txt`, and one of its lines may look like this:

{"PersonID" : 1, "Name" : "Lei", "PersonURI" : "http://www.ldbc.eu/ldbc_socialnet/1.0/data/pers1"}

Depending on implementation, the SUT may refer to persons either by IDs (relational and graph databases) or URIs (RDF systems), so we provide both values for the Person parameter.

Load Definition

LDBC-SNB Test Driver is in charge of the execution of the Interactive Workload. At the begining of the execution, the Test Driver creates a query mix by assigning to each query instance, a query issue time and a set of parameters taken from the generated substitution parameter set described above.
Query issue times have to be carefully assigned. Although substitution parameters are choosen in such a way that queries of the same type take similar time, not all query types have the same complexity and touch the same amount of data. Therefore, if all query instances, regardless of their type, are issued at the same rate, those more complex queries will dominate the execution's result, making faster query types purposeless. To avoid this situation, each query type is assigned a different interleave time. This interleave time corresponds to the amount of time that must elapse between issuing two query instances of the same type. Interleave times have been empirically determined by experimenting with the workload on different existing database technologies. Those more complex query types, will have larger interleave times than those faster queries. Table 2.13 shows the current interleave times assigned to each query type in milliseconds.

Query Type	ms	Query Type	ms
Query 1	30	Query 8	1
Query 2	12	Query 9	40
Query 3	72	Query 10	27
Query 4	27	Query 11	18
Query 5	42	Query 12	34
Query 6	18	Query 13	1
Query 7	13	Query 14	66

Table 2.13: Interleaved latencies for each query type in miliseconds.

The specified interleave times, implicitly define the query ratios between queries of different types, as well as a default target throughput. However the Test Sponsor may specify a different target throughput to test, by

‘squeezing” together or “stretching” further apart the queries of the workload. This is achieved by means of a factor that is multiplied by the interleaved latencies (see 3.2.1). Therefore, different throughputs can be tested while maintaining the relative ratios between the query types.

3.1 Data generation

DATAGEN uses Hadoop to implement the data generation. Detailed instructions to configure hadoop for running DATAGEN can be found at the DATAGEN project software repository[1].

3.1.1 DATAGEN Configuration, Compilation and Execution

DATAGEN is designed to be as easy to configure, compile and execute as possible. With this objective in mind, a *run.sh* script is provided, which handles all the compilation and execution processes. *run.sh* is found in the DATAGEN root folder. DATAGEN uses Apache Maven to download any required dependencies and compile the sources. *run.sh* needs to be configured with two variables pointing to the proper folders. The following is the list of variables to set:

- **HADOOP_HOME**: Points to your hadoop root folder.
- **LDBC_SOCIALNET_DATAGEN_HOME**: Points to your DATAGEN root folder.

Once these variables are properly set, by typing:

```
$ sh run.sh
```

DATAGEN is compiled and executed, and a dataset with the default options is generated in the current folder. A file *params.ini* is used to change the characteristics of the generated network, as well as to set other options. Table 3.1 summarizes the different available options and their default values:

Option	Default	Description
scaleFactor	1	The scale factor of the data to generate. Possible values are: 1, 3, 10, 30, 100, 300 and 1000
serializer	csv	The format of the output data. Options are: csv, csv_merge_foreign, ttl
compressed	false	Specifies to compress the output data in gzip.
outputDir	./	Specifies the folder to output the data.
numThreads	1	Sets the number of threads to use. Only works for pseudo-distributed mode

Table 3.1: Description of the data types.

An example of *params.ini* for scale factor 30, ttl serializer, 4 threads, compressed output and a custom output dir, should look like:

```
scaleFactor:30
serializer:ttl
compressed:true
outputDir:/home/user/output
numThreads:4
```

DATAGEN outputs data into HDFS. The outputDir directory specified in *params.ini* file, will be automatically created in HDFS if it does not exist. If there is not an HDFS file system mounted, then data is output to your local file system.

[1] DATAGEN repository: https://github.com/ldbc/ldbc_snb_datagen

3.1.2 Serializers

LDBC-SNB supports three different output formats: TTL, CSV and CSV_MERGE_FOREIGN. Besides the serializers' specific files, other files are generated: updateStream.csv files, which contains the update queries and is used by the test driver to issue the workload, and the substitution parameters files described in Section 2.3.1.

TTL

This is the standard Turtle[2] format. DATAGEN outputs two files: 0_ldbc_socialnet_static_dbp.ttl and 0_ldbc_socialnet.ttl.

CSV

This is a comma separated format. Each entity, relation and properties with a cardinality larger than one, are output in a separate file. Generated files are summarized at Table 3.2. Depending on the number of threads used for generating the dataset, the number of files varies, since there is a file generated per thread. The * in the file names indicates a number between 0 and $NumberOfThreads - 1$.

[2]Description of the Turtle RDF format http://www.w3.org/TR/turtle/

tagclass_*.csv	id | name | url |
tagclass_isSubclassOf_tagclass_*.csv	TagClass.id|TagClass.id |

Table 3.2: Files output by CSV serializer

CSV_MERGE_FOREIGN

This is a comma separated format. It is similar to CSV, but those relations connecting two entities A and B, where an entity A has a cardinality of one, A is output as a column of entity B. Generated files are summarized at Table 3.3. Depending on the number of threads used for generating the dataset, the number of files varies, since there is a file generated per thread. The * in the file names indicates a number between 0 and

Table 3.3: Files output by CSV_MERGE_FOREIGN serializer

3.2 Running the benchmark

Running a benchmark workload involves a number of steps, including data import, driver configuration and workload execution. The data import step involves loading the output of the data generator into the vendor database, deploying the database and, optionally, performing a warm-up phase. The other steps are explained in the following sections.

3.2.1 Driver Configuration

Before running a benchmark workload the workload driver [1] must be configured, this involves the following steps:

1. Programming: implement a vendor specific database connector (covered in section 3.2.1)
2. Configuration: configure the general driver properties (covered in section 3.2.1)
3. Configuration: configure the workload specific driver properties (covered in 3.2.1)

Vendor specific database connector

Vendors must provide the workload driver with implementations for a number of Java classes: `Db` and `OperationHandler`. More specifically, one implementation of `Db`, (optionally) one implementation of `DbConnectionState` (used to manage shared resources among queries, e.g. network connections), and one implementation of `OperationHandler` per query in the workload.
As a guide, to implement the necessary classes for a workload of two queries (`LdbcQuery1` and `LdbcQuery2`), see the code snippet below. For a more detailed explanation of how this is done refer to the workload driver documentation [1].

```
public class ExampleDbConnectionState extends DbConnectionState {
    private Client client;
    public ExampleDbConnectionState(String url){
        client = new Client(url);
    }

    public getClient(){
        return client;
    }
}

public class ExampleDb extends Db {
    private ExampleDbConnectionState state;

    @Override
    protected void onInit(Map<String, String> properties) throws DbException {
        registerOperationHandler(LdbcQuery1.class, LdbcQuery1Handler.class);
        registerOperationHandler(LdbcQuery2.class, LdbcQuery2Handler.class);
        state = new ExampleDbConnectionState(properties.get(‘‘url’’));
    }

    @Override
    protected void onCleanup() throws DbException {}

    @Override
    protected DbConnectionState getConnectionState() throws DbException {
        return state;
    }

    public static class LdbcQuery1Handler extends OperationHandler<LdbcQuery1> {
        @Override
```

```
        protected OperationResult executeOperation(LdbcQuery1 operation) throws DbException {
            Client client = ((ExampleDbConnectionState)dbConnectionState()).getClient();
            LdbcQuery1Result result = client.execute(operation)
            int resultCode = // typically used for debugging, e.g. to return error codes
            return operation.buildResult(resultCode, result);
        }
    }

    public static class LdbcQuery2ToHandler extends OperationHandler<LdbcQuery2> {
        @Override
        protected OperationResult executeOperation(LdbcQuery2 operation) throws DbException {
            Client client = ((ExampleDbConnectionState)dbConnectionState()).getClient();
            LdbcQuery2Result result = client.execute(operation)
            int resultCode = // typically used for debugging, e.g. returning error codes
            return operation.buildResult(resultCode, result);
        }
    }
}
```

General driver properties

Although a detailed explanation of the workload driver design is beyond the scope of this document, it is worth noting that it has a number of configuration parameters, these parameters are summarized in Table 3.2.1.

status	boolean	intermittently output workload status during execution
operationcount	integer	number of queries to generate
threadcount	integer	size of thread pool to use for query execution
resultfile	string	path to where workload results will be written
timeunit	enum	time unit to report result metrics in
timecompressionratio	double	adjust all query start times proportionally
gctdeltaduration	integer	min duration (ms) between dependent reads and writes
peeridentifiers	string[]	addresses of other driver processes (for distributed mode)
toleratedexecutiondelay	integer	max allowed time between scheduled and actual query start times
workload	string	class name of specific `Workload` implementation
database	string	class name of specific `Db` implementation

Table 3.4: General Driver Parameters

Note that default configuration files, with relevant parameter values set and required parameters commented, are provided in the driver distribution.

Workload specific driver properties

In addition to the general driver properties, the driver supports the definition of arbitrary properties, which are passed along to the pluggable driver components: `Db` and `Workload`. The first, `Db`, was described already in the previous section. The second is `Workload`, it is the class responsible for defining which operations, in which order and at what throughput, the driver will generate. From the point of view of the driver, the LDBC Social Network Benchmark is an implementation of the `Workload` class, in this case named `LdbcInteractiveWorkload`. For more details regarding the workload itself see 2.3.1.
The configuration parameters for the `LdbcInteractiveWorkload` workload are summarized in Table 3.2.1.

3.2.2 Running Workload

Finally, to run the workload execute the `main` method of the `Client` class in the driver. The general pattern for doing so is as follows:

parameter_dir	string	data generator parameters directory (read parameters)
data_dir	string	data generator data directory (dataset and write parameters)
LdbcQuery1_interleave	boolean	interval between successive query 1 executions
LdbcQuery2_interleave	boolean	interval between successive query 2 executions
LdbcQuery3_interleave	boolean	interval between successive query 3 executions
LdbcQuery4_interleave	boolean	interval between successive query 4 executions
LdbcQuery5_interleave	boolean	interval between successive query 5 executions
LdbcQuery6_interleave	boolean	interval between successive query 6 executions
LdbcQuery7_interleave	boolean	interval between successive query 7 executions
LdbcQuery8_interleave	boolean	interval between successive query 8 executions
LdbcQuery9_interleave	boolean	interval between successive query 9 executions
LdbcQuery10_interleave	boolean	interval between successive query 10 executions
LdbcQuery11_interleave	boolean	interval between successive query 11 executions
LdbcQuery12_interleave	boolean	interval between successive query 12 executions
LdbcQuery13_interleave	boolean	interval between successive query 13 executions
LdbcQuery14_interleave	integer	interval between successive query 14 executions
LdbcQuery1_enable	boolean	enable/disable read query 1
LdbcQuery2_enable	boolean	enable/disable read query 2
LdbcQuery3_enable	boolean	enable/disable read query 3
LdbcQuery4_enable	boolean	enable/disable read query 4
LdbcQuery5_enable	boolean	enable/disable read query 5
LdbcQuery6_enable	boolean	enable/disable read query 6
LdbcQuery7_enable	boolean	enable/disable read query 7
LdbcQuery8_enable	boolean	enable/disable read query 8
LdbcQuery9_enable	boolean	enable/disable read query 9
LdbcQuery10_enable	boolean	enable/disable read query 10
LdbcQuery11_enable	boolean	enable/disable read query 11
LdbcQuery12_enable	boolean	enable/disable read query 12
LdbcQuery13_enable	boolean	enable/disable read query 13
LdbcQuery14_enable	boolean	enable/disable read query 14
LdbcUpdate1AddPerson_enable	boolean	enable/disable update query 1
LdbcUpdate2AddPostLike_enable	boolean	enable/disable update query 2
LdbcUpdate3AddCommentLike_enable	boolean	enable/disable update query 3
LdbcUpdate4AddForum_enable	boolean	enable/disable update query 4
LdbcUpdate5AddForumMembership_enable	boolean	enable/disable update query 5
LdbcUpdate6AddPost_enablet	boolean	enable/disable update query 6
LdbcUpdate7AddComment_enable	boolean	enable/disable update query 7
LdbcUpdate8AddFriendship_enable	boolean	enable/disable update query 8

Table 3.5: LDBC Social Network Benchmark Parameters

```
usage: java -cp core-VERSION.jar com.ldbc.driver.Client [-db <classname>] [-del <duration>] [-gctd <duration>]
       [-oc <count>] [-P <file1:file2>] [-p <key=value>] [-pids <peerId1:peerId2>] [-rf <path>] [-s] [-tc
       <count>] [-tcr <ratio>] [-tu <unit>] [-w <classname>]
   -db,--database <classname>                    classname of the DB to use (e.g.
                                                 com.ldbc.driver.workloads.simple.db.BasicDb)
   -del,--toleratedexecutiondelay <duration>     duration (ms) an operation handler may miss its scheduled
                                                 start time by
   -gctd,--gctdeltaduration <duration>           safe duration (ms) between dependent operations
   -oc,--operationcount <count>                  number of operations to execute (default: 0)
   -P <file1:file2>                              load properties from file(s) - files will be loaded in the
```

```
                                          order provided
                                          first files are highest priority; later values will not
                                          override earlier values
   -p <key=value>                         properties to be passed to DB and Workload - these will
                                          override properties loaded from files
   -pids,--peeridentifiers <peerId1:peerId2>  identifiers/addresses of other driver workers (for
                                          distributed mode)
   -rf,--resultfile <path>                where benchmark results JSON file will be written (null =
                                          file will not be created)
   -s,--status                            show status during run
   -tc,--threadcount <count>              number of worker threads to execute with (default: 2)
   -tcr,--timecompressionratio <ratio>    change duration between operations of workload
   -tu,--timeunit <unit>                  time unit to use when gathering metrics.
                                          default:MILLISECONDS, valid:[NANOSECONDS, MICROSECONDS,
                                          MILLISECONDS, SECONDS, MINUTES]
   -w,--workload <classname>              classname of the Workload to use (e.g.
                                          com.ldbc.driver.workloads.simple.SimpleWorkload)
```

For the Interactive workload of LDBC-SNB it is necessary to provide the driver with four configuration files, containing: general driver properties, workload specific driver properties (e.g. database connection string), a dataset specific value for one of the general driver properties (specifically, `gctdeltaduration`), and vendor specific database properties. The commandline to execute the workload would look something like:

```
java -cp ldbc_driver/target/core-0.2-SNAPSHOT.jar com.ldbc.driver.Client
-db com.vendor.VendorDb
-P vendor/vendor.properties,
-P data_generator/outputDir/updateStream_0.properties,
-P ldbc_driver/workloads/ldbc/socnet/interactive/ldbc_socnet_interactive.properties
-P ldbc_driver/src/main/resources/ldbc_driver_default.properties
```

3.3 Gathering the results

Gathering the results for a benchmark run is a simple matter of referring to the results JSON file emitted by the driver. The format of that file is as follows:

```
{
  "unit": "MILLISECONDS",
  "start_time": 1400750662691,
  "finish_time": 1400750667691,
  "total_duration": 5000,
  "total_count": 50,
  "all_metrics": [
    {
      "name": "Query1",
      "count": 50,
      "unit": "MILLISECONDS",
      "run_time": {
        "name": "Runtime",
        "unit": "MILLISECONDS",
        "count": 50,
        "mean": 100,
        "min": 2,
        "max": 450,
        "50th_percentile": 98,
        "90th_percentile": 129,
        "95th_percentile": 432,
        "99th_percentile": 444
      },
      "start_time_delay": {
        "name": "Start Time Delay",
```

```
        "unit": "MILLISECONDS",
        "count": 7,
        "mean": 3.5714285714285716,
        "min": 0,
        "max": 25,
        "50th_percentile": 0,
        "90th_percentile": 0,
        "95th_percentile": 25,
        "99th_percentile": 25
      },
      "result_code": {
        "name": "Result Code",
        "unit": "Result Code",
        "count": 50,
        "all_values": {
          "0": 42,
          "1": 8
        }
      }
    }
  ]
}
```

3.4 Validation

LDBC-SNB driver provides a validation mechanism to test the correctness of a benchmark workload implementation. To use it, one must provide a validation dataset, which contains the following items:

- a set of substituion parameters;
- a set of expected results;
- the dataset;
- a driver configuration file.

Validation datasets are provided by LDBC-SNB, and can be found in the official github LDBC repository. Once the vendor has implemented the workload, it must load the provided dataset and run the benchmark with the "validatedatabase" option set. With this option, the driver will read the file with the expected results, and compare them with the results obtained by the vendor. For more information visit the ldbc driver page.
